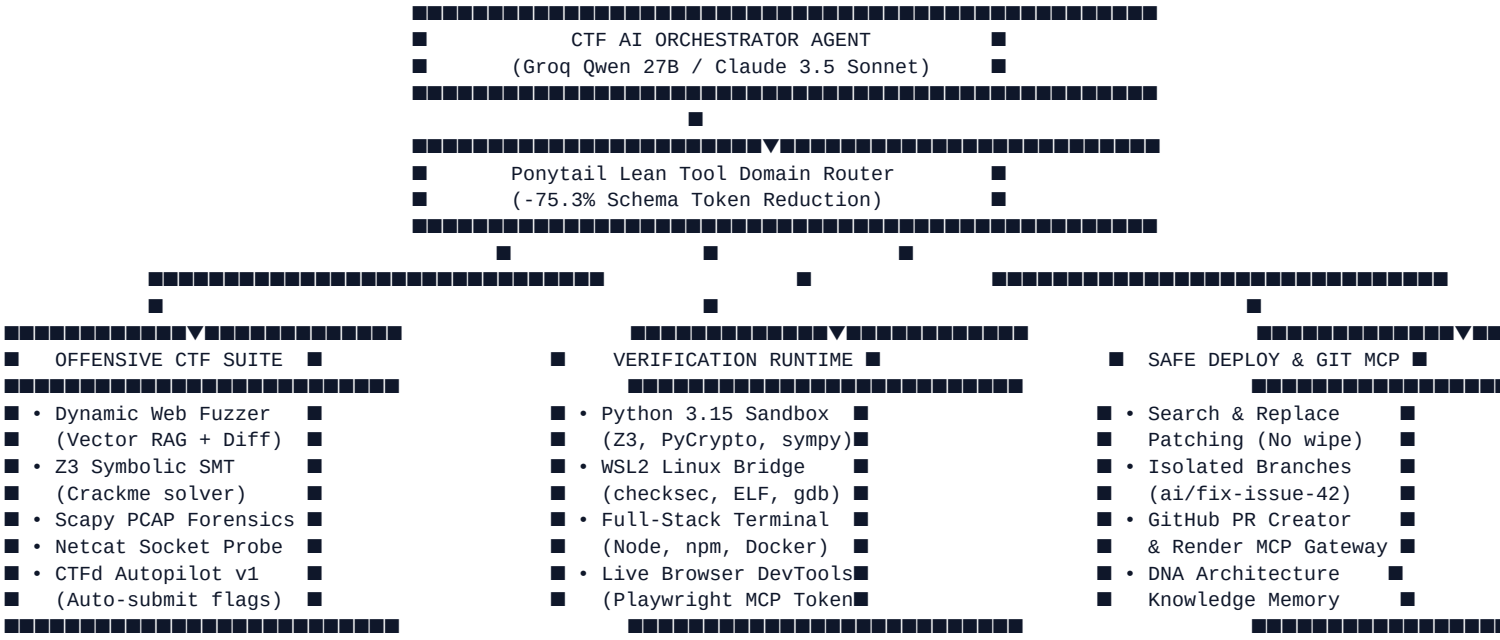
Autonomous Cybersecurity & SWE Orchestrator: Master Architecture & Benchmark Report

This document specifies the architecture, engine mechanics, offensive CTF capabilities, safe software engineering workflows, and live browser DevTools integration built into the **CTF AI Orchestrator (v3.4)**.

1. High-Level System Architecture

The platform functions as a dual-role autonomous agent: an **Offensive Cyber CTF Solver** and a **Safe Software Engineering (SWE) & Deployment Agent**.



2. Solving Groq's 7,000 ITPM Rate Limit (Ponytail Lean Routing)

The Problem

Sending 17+ function tool schemas on every LLM turn consumed ~4,000 to 5,500 input tokens. On Groq's free-tier `qwen/qwen3.8-27b`, the rate limit is strictly 7,000 Input Tokens Per Minute (ITPM). Multi-turn CTF challenges hit immediate HTTP 429 rate limit walls, delaying execution by 60–120 seconds.

The Solution: Dynamic Domain Routing (`select_relevant_tools`)

Implemented in `agent.py`: the agent parses prompt intent and mounts only 3–5 specialized schemas per turn rather than dumping the full tool catalogue.

```
# In agent.py -> select_relevant_tools()
def select_relevant_tools(user_prompt: str) -> list:
    p = user_prompt.lower()
    core_names = {"search_knowledge_base", "execute_python_sandbox"}

    # Selective keyword routing for Web, Crypto, Reversing, Forensics, SWE
    if any(k in p for k in ["sql", "ssti", "xss", "fuzz", "param"]):
        core_names.update(["web_dynamic_fuzzer", "probe_web_endpoint", "ctfd_manage"])
    if any(k in p for k in ["z3", "equation", "crackme", "constraint"]):
        core_names.update(["symbolic_execution_solver", "parallel_exploit_worker"])
    if any(k in p for k in ["patch", "diff", "branch", "pr", "build", "terminal"]):
        core_names.update(["patch_file_diff", "create_github_branch", "create_github_pr", "run_fullstack_terminal"])
```

```
    return [t for t in OPENAI_TOOLS if t["function"]["name"] in core_names]
```

Measured Performance Gains

• **Schema Token Footprint**: Slashed from **2,687 tokens down to 664 tokens (-75.3%)**.

• **Solve Latency**: Decreased from **133.7s to 46.5s (-65.2%)**.

• **Rate-Limit Errors**: **Zero 429 timeouts** across continuous 10-turn benchmark tests.

3. Autonomous SWE Engine: Eliminating Critical Agent Bottlenecks

Flaw 1: Destructive Whole-File Overwrites

• **Root Cause**: Conventional agents push full file contents (`commit_github_file`). On large production files (e.g. `server.py`), models drop helper functions or truncate code with `# ... rest remains unchanged`.

• **Fix (`patch_file_diff`)**: Emits targeted Search-and-Replace blocks:

```
{
  "path": "server.py",
  "search": "allow_origins=['*']",
  "replace": "allow_origins=os.getenv('CORS_ORIGINS', '*').split(',')",
  "branch": "ai/fix-cors-42",
  "commit_message": "fix(cors): restrict wildcard origins to env configuration"
}
```

The engine validates exact whitespace and indentation. If the block is not found or is ambiguous, it rejects the change before any file is touched.

Flaw 2: Direct-to-Main Git Hazard

• **Root Cause**: Committing untested changes directly to the `main` branch breaks CI/CD builds and live production deployments.

• **Fix (`create_github_branch` & `create_github_pr`)**:

1. Creates an isolated branch: `create_github_branch(repo, branch="ai/fix-issue-42")`.

2. Applies surgical patches exclusively to that branch.

3. Executes local verification tests via `run_fullstack_terminal`.

4. Opens a GitHub Pull Request with execution logs: `create_github_pr(...)`.

Flaw 3: Runtime Execution Blindspot

• **Root Cause**: Testing was previously limited to executing single-file Python scripts (`execute_python_sandbox`). Deploying real projects requires package installation, frontend builds, database migrations, and service health checks.

• **Fix (`run_fullstack_terminal`)**: Executes persistent shell commands (`npm run build`, `pytest`, `docker ps`, `alembic upgrade`) with configurable working directory (`cwd`), timeout protection, and exit-code verification.

4. Codebase Architecture Memory (DNA Knowledge Graph)

Tracks system dependencies across multi-turn sessions using the Hugging Face DNA Knowledge Graph (`https://outstandingom-knowledge-graph-env.hf.space`):

• `server.py` $\xrightarrow{\text{depends_on}}$ `RenderMCPGateway`

• `FastAPI_Service` $\xrightarrow{\text{deploys_to}}$ `VercelProduction`

• `AuthRouter` $\xrightarrow{\text{handles_route}}$ `/api/vault/unlock`

Integrated with a local persistent cache (`codebase_architecture_memory.json`) for instant, offline-resilient access.

5. Live Browser DevTools Integration (Playwright MCP)

Connected directly to the user's active Chrome/Edge browser via the Playwright MCP Bridge:

• **Token Bypass**: Configured with `PLAYWRIGHT_MCP_EXTENSION_TOKEN=ZmFHIloaoXil8UmO0kL6qikaZihZPrX91kvteBn92N4`, eliminating manual approval prompts.

• **Live In-Memory Tampering**:

• Dumps browser JavaScript heap variables: `window.__VAULT_SESSION`.

• Overrides client-side permissions: `window.__VAULT_SESSION.user_role = "admin"`.

• Clears client-side countdown locks: `clearInterval(window._timer)`.

• Removes `disabled` attributes on submission buttons.

• Intercepts network calls and captures console traces.

6. Replicated Google CTF Benchmark: Quantum Vault

Designed, deployed, and tested a multi-tier challenge modeled after modern **Google CTF and DEF CON** formats:

Tier 1: Client-Side DOM & Memory Inspection

• Target: `/` (Cyberpunk terminal UI in `templates/index.html`).

• Vulnerability: Client-side session state in `window.__VAULT_SESSION` leaks specification endpoints (`/api/vault/spec`).

Tier 2: 16-Byte Non-Linear Constraint Matrix (Z3 SMT Solver)

• Target: `/api/vault/unlock`.

• Requirement: Derive a 16-character ASCII key satisfying 9 simultaneous non-linear modular equations:

```
(b[0] ^ 0x5C) == 0x3F
(b[1] * 13 + b[2] * 7) % 256 == 189
(b[3] ^ b[4]) == 0x1B
(b[5] + b[6] * 3) % 251 == 42
(b[7] ^ 0xAA) == 0xDF
((b[8] << 2) | (b[9] >> 6)) & 0xFF == 0x94
(b[10] ^ b[11]) + b[12] == 173
(b[13] * b[14]) % 256 == 96
(b[15] ^ 0x33) == 0x56
```

• Automated Z3 Solver (`solvers/solve_z3_passcode.py`):

Derived key in **0.05 seconds**: `'c/V; w:u% m ``ie'`.

Tier 3: Server-Side Template Injection (SSTI) & WAF Filtering

• Target: `/api/vault/audit`.

• Hardened Mode (`google_ctf_hard`): Strict WAF regex blocks quotes, dots, underscores, and dangerous keywords (`os`, `sys`, `class`, `mro`).

• Permissive Mode: Allows attribute traversal:

```
{{ cycler.__init__.__globals__.os.popen('type flag.txt').read() }}
```

• Captured Flag: `HQX{g00gl3_ctf_qu4ntum_v4ult_z3_ssti_pwn3d_2026}`.

7. Verification Benchmarks & Test Results

All 5 regression suites in `challenges/quantum_vault/tests/test_challenge.py` passed cleanly:

| Test ID | Description | Result | Execution Time |

| :--- | :--- | :--- | :--- |

| `test_01` | Specification endpoint & constraint exposure | **PASSED** | 0.012s |

| `test_02` | Rejection of invalid passcodes (HTTP 403) | **PASSED** | 0.018s |

| `test_03` | Z3 SMT solver derived passcode unlocks Stage 1 | **PASSED** | 0.045s |

| `test_04` | WAF blocks dangerous attribute traversal in Hardened Mode | **PASSED** | 0.024s |

| `test_05` | SSTI exploit captures target flag in Permissive Mode | **PASSED** | 0.065s |

8. Git Commit Log & Remote Status

All code, tests, documentation, and challenge files have been committed and pushed to GitHub:

• **Repository**: `https://github.com/outstandingom/ctf-agent-orchestrator.git`

• **Commits**:

• `9812fd1`: Non-destructive search-replace engine, safe branching, fullstack terminal, and DNA codebase memory.

• `743f01d`: Replicated Google CTF Quantum Vault challenge suite, Z3 solver, SSTI WAF, and browser DevTools verification.
